

1. Entity:

What can be counted as an entity?

Usually, an icon with text or a box of text can be counted as an entity.

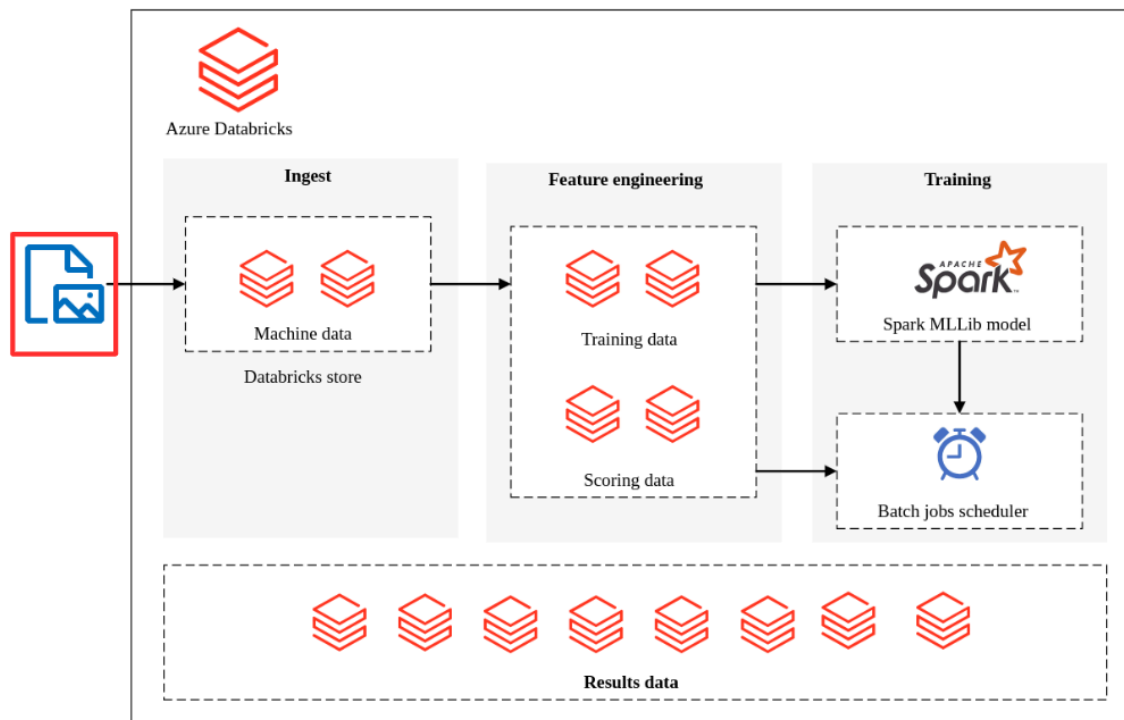

```
'entity_0': {'name': 'Email servers'},
```

```
'entity_0': {'name': 'Ticker symbol'},  
'entity_1': {'name': 'Model, Exchange symbol mapping knowledge'},  
'entity_2': {'name': 'Stock analysis agent'},
```

What cannot be counted as an entity?

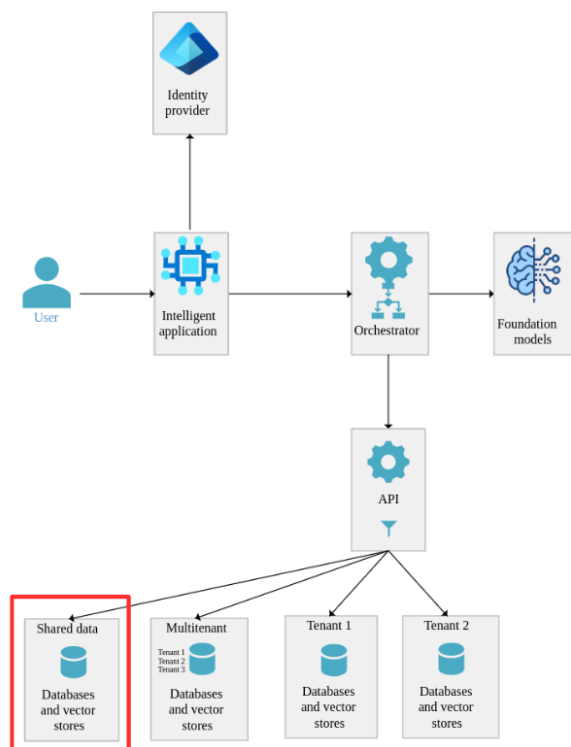

In this example, the icon in the red box does not have text. It is hard to locate the entity without a name based on our JSON format. Therefore, we give up this diagram.

The entity has the following property:

- name

The name of the entity:

Usually, the name is the text underneath the icon. But there are exceptions.

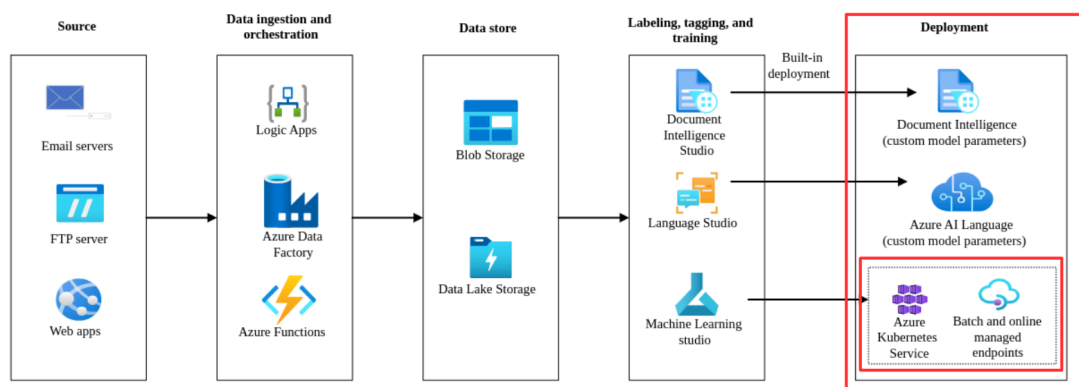

In this example, the whole text is counted as the name of the entity.

```
'entity_5': {'name': 'Shared data Databases and vector stores'},
```

2. Cluster:

What can be counted as a cluster?

Usually, a cluster is a box that contains at least one entity. It does not have to contain text.

In this example, we have two clusters, one of which does not have a name. `'Cluster_5'`
`'include_cluster': ['cluster_4',`

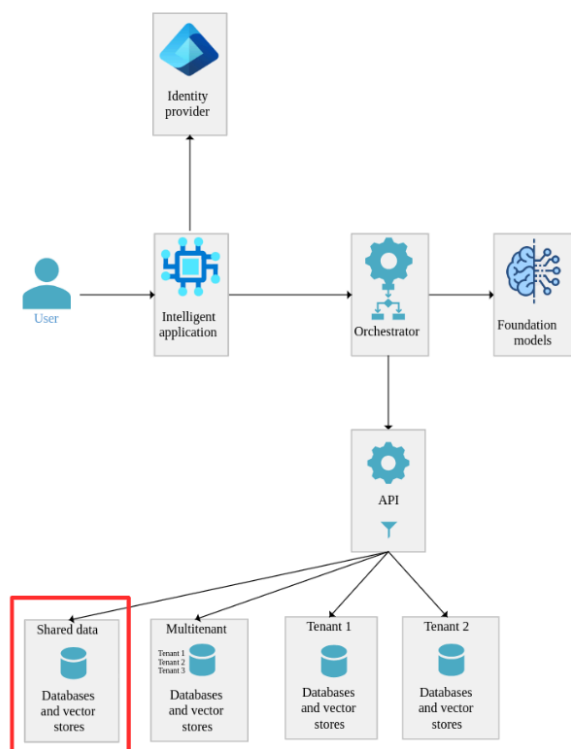

```

'entity_11': {'name': 'Document Intelligence (custom model parameters)'},
'entity_12': {'name': 'Azure AI Language (custom model parameters)'},
'entity_13': {'name': 'Azure Kubernetes Service'},
'entity_14': {'name': 'Batch and online managed endpoints'},

'cluster_4': {'name': '', 'include_entity': ['entity_13', 'entity_14'],
'include_cluster': []},
'cluster_5': {'name': 'Deployment', 'include_entity': ['entity_11',
'entity_12', 'entity_13', 'entity_14'], 'include_cluster': ['cluster_4']},

```

What does not have to be counted as a cluster?

In this example, because the box only contains one entity, it does not have to be a cluster. Also, based on the style of the whole diagram, almost every entity has a gray box.

The cluster has the following property:

- **name** (can be "")
- **Include_entity**
- **Include_cluster** (can be [])

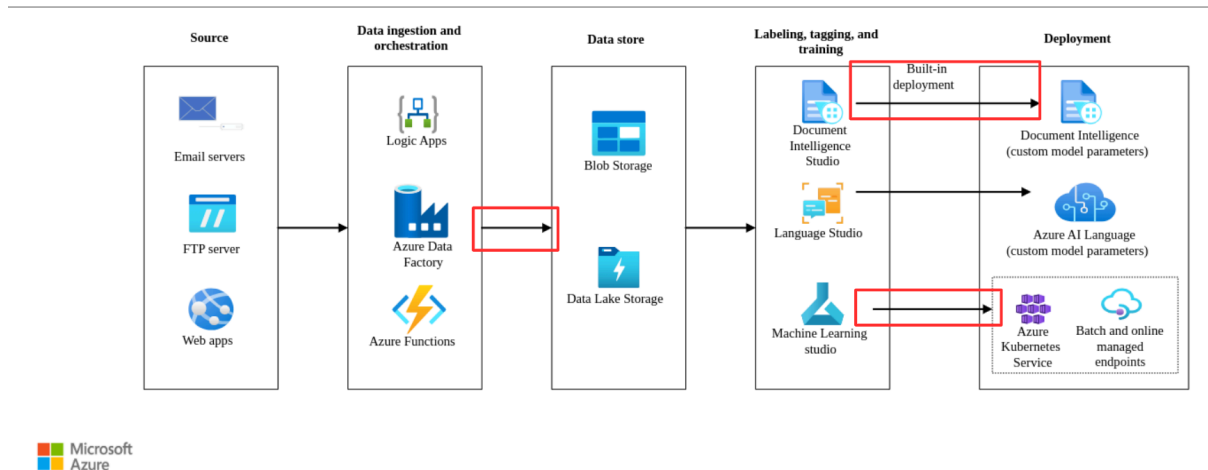

3. Relation:

What can be counted as a relation?

Usually, the link between entities, between clusters, and between an entity and a cluster can be counted as a relation.

The relation has the following properties:

- **source**
- **target**
- **name** (can be '')
- **direction** (can only be single, double, or none)

How to judge whether the source or target is an entity or a cluster?

As illustrated in the example above,

The left red box is a 'cluster2cluster' relation

The top right red box is an 'entity2entity' relation

The bottom right red box is an 'entity2cluster' relation

```
{'source': 'cluster_3', 'target': 'cluster_4', 'name': '', 'direction': 'single'},
{'source': 'entity_8', 'target': 'entity_11', 'name': 'Built-in deployment', 'direction': 'single'},
{'source': 'entity_10', 'target': 'cluster_4', 'name': '', 'direction': 'single'},
```
